

MODULE END ASSIGNMENT – SUMMARY REPORT

Analyzing E-Learning Platform Purchases using MySQL

Project Summary

This project was developed using MySQL to analyze the purchase data of an e-learning platform. Three tables (learners, courses, and purchases) were created with primary key and foreign key relationships. Sample data was inserted, and SQL queries were used to analyze learner purchases, course performance, and sales.

Key Insights

- The database successfully stores learners, courses, and purchase details.
- INNER, LEFT, and RIGHT JOINS were used to combine data from multiple tables.
- Total spending of each learner was calculated.
- The top purchased courses were identified.
- Revenue and unique learners were analyzed for each course category.
- Learners who purchased from multiple categories were identified.
- Courses with no purchases were detected.
- CTE, CASE, IFNULL, and VIEW were used to perform advanced SQL analysis.

Recommendations

- Focus marketing efforts on the top-performing course categories.
- Improve the promotion of courses with low or no purchases.
- Offer personalized recommendations to high-value learners.
- Introduce discounts for less popular courses to increase sales.
- Regularly analyze purchase trends to improve business decisions.

Conclusion

This project demonstrates how MySQL can be used to manage and analyze e-learning platform data efficiently. SQL queries help generate meaningful business insights, enabling better decision-making and improving overall platform performance.
